Description:

The Python dictionary accesses its keys by hash values for performance reasons. As a result there is no specified order of its elements. Consequently there are no sort or slicing methods on ordinary dictionaries.

A little German-English dictionary:

>>> seqdict.mseqdict()

'F1\366te': ['flute']})

```
dict={"Abend" : "evening",
    "aber" : "but",
    "Bild" : "picture",
    "deshalb" : "therefore",
    "Erkennung" : "recognition",
    "Flöte" : "flute",
    "gewinnen" : "gain" }
>>> dict
{'gewinnen': 'gain', 'deshalb': 'therefore', 'Abend': 'evening', 'aber':
'but', 'Bild': 'picture', 'Erkennung': 'recognition', 'Fl\366te': 'flute' }
```

Although the dictionary was created with items in order there is no order and no reliable sequence in the dictionary's representation.

The sequential multiple value dictionary incorporates a list holding the dictionary's keys and the dictionary with multiple values in a UserList.

An empty sequential multiple value dictionary (mseqdict):

```
mseqdict(
                 # list holds the keys in sequence
[],
{})
                 # dictionary holds the keys and values
A msegdict instance of dict is created:
>>> s = seqdict.mseqdict(dict)
>>> s
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te'],
{'gewinnen': ['gain'], 'deshalb': ['therefore'], 'Abend': ['evening'],
'aber': ['but'], 'Bild': ['picture'], 'Erkennung': ['recognition'],
'Fl\366te': ['flute']})
After sorting:
>>> s.sort(lambda x,y:cmp(string.lower(x),string.lower(y)))
>>> s
mseqdict(
['Abend', 'aber', 'Bild', 'deshalb', 'Erkennung', 'Fl\366te', 'gewinnen'],
{'gewinnen': ['gain'], 'deshalb': ['therefore'], 'Abend': ['evening'],
```

'aber': ['but'], 'Bild': ['picture'], 'Erkennung': ['recognition'],

```
Voila, here it is sorted again!
>>> for key, value in s.items():
           print '%11s : %s'%(key,value[0])
. . .
          Abend : evening
       aber : but
Bild : picture
deshalb : therefore
     Erkennung : recognition
          Flöte : flute
      gewinnen : gain
Of course, keys and items also appear in sorted sequence:
>>> s.keys()
['Abend', 'aber', 'Bild', 'deshalb', 'Erkennung', 'Fl\366te', 'gewinnen']
>>> s.values()
[['evening'], ['but'], ['picture'], ['therefore'], ['recognition'],
['flute'], ['gain']]
>>> s.items()
[('Abend', ['evening']), ('aber', ['but']), ('Bild', ['picture']),
('deshalb', ['therefore']), ('Erkennung', ['recognition']), ('Fl\366te',
['flute']), ('gewinnen', ['gain'])]
A short Tutorial:
slicing by index:
>>> s[2:5]
mseqdict(
['Bild', 'deshalb', 'Erkennung'],
{'Bild': ['picture'], 'Erkennung': ['recognition'], 'deshalb':
['therefore']})
insert:
>>> d=seqdict.mseqdict({"Fliege":"fly","Hand":"hand"})
>>> s.insert(3,d)
>>> s
mseqdict(
['Abend', 'aber', 'Bild', 'Hand', 'Fliege', 'deshalb', 'Erkennung',
'Fl\366te', 'gewinnen'],
{'Hand': ['hand'], 'Fliege': ['fly'], 'gewinnen': ['gain'], 'deshalb':
['therefore'], 'Abend': ['evening'], 'aber': ['but'], 'Bild': ['picture'],
'Erkennung': ['recognition'], 'F1\366te': ['flute']})
append:
>>> x=seqdict.mseqdict(dict)
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> x.append('Zug','train')
>>> x.append('Bild','illustration')
```

```
>>> x
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te',
'Zug'],
{'gewinnen': ['gain'], 'deshalb': ['therefore'], 'Zug': ['train'], 'Abend':
['evening'], 'aber': ['but'], 'Bild': ['picture', 'illustration'],
'Erkennung': ['recognition'], 'Fl\366te': ['flute']})
check:
Checks the integrity of the dictionary. This method is suitable for debugging reasons.
>>> x.check()
1 # ok
>>> x.list[0]='spam' # don't even think to modify internals!
>>> x.check()
0 # list and dict are of same length, but keys don't match
                      # don't even think to modify internals!
>>> del x.list[1]
>>> x.check()
-1 # list and dict are not of same length
clear:
>>> x.clear()
>>> x
mseqdict(
[],
{})
>>> s1=s.copy() # copy of the dictionary
>>> s3=s
                  # copies the reference
>>> s==s1==s2==s3
>>> s is s1 or s is s2 or s1 is s2
>>> s is s3
count:
Counts the number of appearance of the value within the dictionary's values
>>> u=segdict.msegdict({1:2, 2:3, 3:4, 4:5, 5:3})
>>> u.count(2)
1
>>> u.count(3)
>>> u[1] = 3
>>> u.count(3)
del:
>>> x=seqdict.mseqdict(dict)
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> del x[1:3]
```

```
>>> x.keys()
['gewinnen', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> del x['Erkennung']
>>> x.keys()
['gewinnen', 'aber', 'Bild', 'Fl\366te']
>>> x['Bild']='painting'
>>> x['Bild']
['picture','painting']
>>> del x['Bild'][0]
>>> x['Bild']
['painting']
>>> del x['Bild'][0]
>>> x.has_key('Bild')
>>> del x
>>> x
Traceback (innermost last):
  File "<stdin>", line 1, in ?
NameError: x
extend:
update:
Unless the keys are member of s they will be appended, otherwise updated.
>>> s.keys()
['Abend', 'Bild', 'Erkennung', 'Hand', 'Fliege', 'Fl\366te', 'aber', 'deshalb', 'gewinnen']
>>> s.values()
[['evening'], ['picture'], ['recognition'], ['hand'], ['fly'], ['flute'], ['but'], ['therefore'], ['gain']]
>>> d["Melone"]="melon"
>>> d["Bild"]="painting"
>>> d.keys()
['Hand','Fliege','Melone']
>>> s.extend(d) # same as s.update(d)
>>> s.keys()
['Abend', 'Bild', 'Erkennung',
'deshalb', 'gewinnen','Melone']
                                  'Hand', 'Fliege', 'Fl\366te', 'aber',
>>> s.values()
[['evening'], ['picture', 'painting'], ['recognition'], ['hand'], ['fly'],
['flute'], ['but'], ['therefore'], ['gain'], ['melon']]
filter:
The filter function considers if the second parameter is:
      0: only keys
      1: key and values
      2: key and value
>>> x=seqdict.mseqdict(dict)
>>> x['Bild'] = 'painting'
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
```

```
>>> import re
>>> x.filter(re.compile('a',re.I).match) # all keys beginning with a or A
segdict(
['Abend', 'aber'],
{'Abend': ['evening'], 'aber': ['but']})
>>> def filter_a(key, values): #filters values with 'a' in value
      for value in values:
. . .
          for i in value:
. . .
            if i == 'a':return 1
. . .
      return 0
>>> x.filter(filter_a,1) #filters key, values
mseqdict(
['gewinnen', 'Bild'],
{'Bild': ['picture', 'painting'], 'gewinnen': ['gain']})
>>> x.filter(filter_a,2) #filters key,value
mseqdict(
['gewinnen', 'Bild'],
{'Bild': ['painting'], 'gewinnen': ['gain']})
get:
>>> x.get('car') # No return value, as 'car' is not a key of s
>>> x.get('car','key not available')
'key not available'
>>> x.get('Bild')
['picture', 'painting']
index:
>>> x.index("Abend")
2
items:
>>> s.items()
[('gewinnen', ['gain']), ('deshalb', ['therefore']), ('Abend', ['evening']),
('aber', ['but']), ('Bild', ['picture', 'painting']), ('Erkennung',
['recognition']), ('Fl\366te', ['flute'])]
has_key:
>>> x.has_key('car')
>>> x.has_key('Abend')
1
keys():
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
```

```
len:
>>> len(x)
map:
The map function considers if the second parameter is:
       1: kev and values
       2: key and value #default
>>> cntval = lambda key, value: (key, len(value))
>>> x=segdict.msegdict(dict)
>>> x["Bild"]="painting"
>>> x.map(cntval) # Count all value's characters
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te'],
{'gewinnen': [4], 'deshalb': [9], 'Abend': [7], 'aber': [3], 'Bild': [7, 8],
'Erkennung': [11], 'Fl\366te': [5]})
>>> import operator
>>> cntvals = lambda key,values:(key,reduce(operator.add,map(len,values)))
>>> x.map(cntvals,1) # Count the sum of all value's characters
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te'], {'gewinnen': [4], 'deshalb': [9], 'Abend': [7], 'aber': [3], 'Bild': [15], 'Erkennung': [11], 'Fl\366te': [5]})
pop:
push:
You can use the dictionary like a stack
>>> x.pop()
{'F1\366te': ['flute']}
>>> x.push('Auto','car')
>>> x.pop('deshalb')
{'deshalb': ['therefore']}
>>> x
mseqdict(
['gewinnen', 'Abend', 'aber', 'Bild', 'Erkennung', 'Auto'],
{'Auto': ['car'], 'gewinnen': ['gain'], 'Abend': ['evening'], 'aber':
['but'], 'Bild': ['picture', 'painting'], 'Erkennung': ['recognition']})
>>> x.pop('Bild','picture') #pop single values
{'Bild':'picture'}
>>> x['Bild']
'painting'
>>> x.pop('Bild','painting')
{'Bild','painting'}
>>> x.has key('Bild')
```

```
reduce:
>>> x=seqdict.mseqdict(dict)
>>> x['Bild']='painting'
>>> import string
>> g=lambda x,(u,v):('%s%10s: %s\n'%(x,u,string.join(v,',')))
>>> x.reduce(g,'')
' gewinnen : gain\012 deshalb : therefore\012
                                                      Abend : evening\012
                Bild : picture, painting\012 Erkennung : recognition\012
aber : but\012
F1\366te : flute\012'
>>> print x.reduce(g,'')[:-1]
  gewinnen : gain
   deshalb : therefore
     Abend : evening
      aber : but
      Bild : picture, painting
 Erkennung : recognition
     Flöte : flute
remove:
del:
>>> x=seqdict.mseqdict(dict)
>>> x['Bild']='painting'
>>> x.remove('deshalb')
>>> x.remove('Bild','picture')
>>> x.has key('deshalb')
>>> x['Bild']
['painting']
>>> del x['Bild'][0]
x.has key('Bild']
>>> del x['aber']
x.has_key('aber')
>>> x.keys()
['gewinnen', 'Abend', 'Erkennung', 'Fl\366te']
>>> del x[1:3]
>>> x.keys()
['gewinnen', 'F1\366te']
>>> del x
>>> x
Traceback (innermost last):
 File "<stdin>", line 1, in ?
```

NameError: x

reverse:

```
>>> x=seqdict.mseqdict(dict)
>>> x.keys()
['qewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> x.reverse()
>>> x.keys()
['Fl\366te', 'Erkennung', 'Bild', 'aber', 'Abend', 'deshalb', 'gewinnen']
slice: # slicing by key
Slicing with the "['key1':'key2'] is not possible as python accept integer indexes only within this
construct. Thus the slice method implements this as an ordinary function call. An extension is slicing by
step.
>>> x=seqdict.mseqdict(dict)
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> x.slice('Bild')
msegdict(
['Bild'],
{'Bild': ['picture']})
>>> x.slice('deshalb','Erkennung')
mseqdict(
['deshalb', 'Abend', 'aber', 'Bild'],
{'Abend': ['evening'], 'aber': ['but'], 'Bild': ['picture'], 'deshalb':
['therefore']})
>>> x.slice('deshalb','Erkennung',2)
mseqdict(
['deshalb', 'aber'],
{'aber': ['but'], 'deshalb': ['therefore']})
sort:
The sort method allows sorting of keys and/or values
>>> x=segdict.msegdict(dict)
>>> x['Bild']='painting'
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> x.sort()
                       #ASCII-Sort
>>> x.keys()
['Abend', 'Bild', 'Erkennung', 'Fl\366te', 'aber', 'deshalb', 'gewinnen']
>>> sort=lambda x,y:cmp(string.lower(x),string.lower(y))
>>> x.sort(sort)
                       #only the keys will be sorted
>>> x.keys()
['Abend', 'aber', 'Bild', 'deshalb', 'Erkennung', 'Fl\366te', 'gewinnen']
>>> x['Bild']
['picture', 'painting']
>>> x.sort(sort,sort) #2nd function-argument sorts values
>>> x['Bild']
['painting', 'picture']
```

```
>>> x=seqdict.mseqdict(dict)
>>> x['Bild']='painting'
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
>>> nosort = lambda x,y:0
>>> x.sort(nosort)  #use x(nosort,sort) if keys shall not be sorted
>>> x.keys()
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te']
```

split:

The split-method returns a new sequential dictionary (seqdict). It expects a function which accepts a key and a value of the dictionary. If the function returns a key 'tkey' the dictionary-item is copied into the new seqdict (t) as t[tkey][key]=value. For every tkey a seqdict is hold as value.

Following example splits the sequict u into one sequict for every lowercase beginning letter. The lowercase beginning letter is the key and the splitted sequict is the value for the new sequict su.

```
>>> x=seqdict.mseqdict(dict)
>>> x['Bild']='painting'
>>> sort=lambda x,y:cmp(string.lower(x),string.lower(y))
>>> x.sort(sort,sort)
>>> x.keys()
['Abend', 'aber', 'Bild', 'deshalb', 'Erkennung', 'Fl\366te', 'gewinnen']
>>> xsplit = x.split(lambda i:string.lower(i)[0])
>>> xsplit
seqdict(
['a', 'b', 'd', 'e', 'f', 'g'],
{'f': mseqdict(
['F1\366te'],
{'Fl\366te': ['flute']}), 'g': mseqdict(
['gewinnen'],
{'gewinnen': ['gain']}), 'd': mseqdict(
['deshalb'],
{'deshalb': ['therefore']}), 'e': msegdict(
['Erkennung'],
{'Erkennung': ['recognition']}), 'b': mseqdict(
['Bild'],
{'Bild': ['painting', 'picture']}), 'a': mseqdict(
['Abend', 'aber'],
{'Abend': ['evening'], 'aber': ['but']})})
>>> for tkey in xsplit.keys():
... print tkey , xsplit[tkey].keys()
. . .
a ['Abend', 'aber']
b ['Bild']
d ['deshalb']
e ['Erkennung']
f ['Fl\366te']
g ['gewinnen']
```

swap:

This method can only be applied when all values of the dictionary are immutable. The Python dictionary cannot hold mutable keys! So swap doesn't work if only one of the values has the type list or dictionary. Tuples and instances of classes are save as long as they don't emulate lists or dictionaries.

```
>>> x=seqdict.mseqdict(dict)
          # A small German - English dictionary
>>> x
>>> x['Bild']='painting'
>>> x['Ziel']='goal'
>>> x['Tor'] ='qoal'
>>> x
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te',
'Ziel', 'Tor'],
{'Tor': ['goal'], 'Ziel': ['goal'], 'gewinnen': ['gain'], 'deshalb':
['therefore'], 'Abend': ['evening'], 'aber': ['but'], 'Bild': ['picture',
'painting'], 'Erkennung': ['recognition'], 'Fl\366te': ['flute']})
>>> x.swap()
['gain', 'therefore', 'evening', 'but', 'picture', 'painting',
'recognition', 'flute', 'goal'],
{'but': ['aber'], 'recognition': ['Erkennung'], 'painting': ['Bild'],
'flute': ['Fl\366te'], 'gain': ['gewinnen'], 'goal': ['Ziel', 'Tor'], 'evening': ['Abend'], 'therefore': ['deshalb'], 'picture': ['Bild']})
operator +:
>>> x1=x[:3]
>>> x1.keys()
['Abend', 'aber', 'Bild']
>>> x2=x[3:]
>>> x2.keys()
['deshalb', 'Erkennung', 'Fl\366te', 'gewinnen']
>>> x3=x1+x2
>>> x3==x
operator %:
>>> print """'Bild' is the German word for %(Bild)s and
... 'Flöte' is %(Flöte)s in English"""%x
'Bild' is the German word for ['painting', 'picture'] and
'Flöte' is ['flute'] in English
```

Initialising the dictionary:

The msegdict dictionary can be initialised with Python dictionary or Python dictionary emulations.

```
An empty mseqdict:
>>> segdict.msegdict()
mseqdict(
[],
{})
4 ways to initialize the segdict, the values can be segdict or msegdict values:
>>> d1=seqdict.mseqdict(dict.keys(),dict.values())
>>> d2=segdict.msegdict(dict.keys(),dict)
>>> d3=seqdict.mseqdict(dict)
>>> seqdict.mseqdict(dict)
mseqdict(
['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung', 'Fl\366te'],
{'gewinnen': ['gain'], 'deshalb': ['therefore'], 'Abend': ['evening'],
'aber': ['but'], 'Bild': ['picture'], 'Erkennung': ['recognition'],
'F1\366te': ['flute']})
>>> #Now, copy back the textual representation:
>>> d4=segdict.msegdict(
   . ['gewinnen', 'deshalb', 'Abend', 'aber', 'Bild', 'Erkennung',
'F1\366te'],
... {'gewinnen': ['gain'], 'deshalb': ['therefore'], 'Abend': ['evening'], 'aber': ['but'], 'Bild': ['picture'], 'Erkennung': ['recognition'],
'F1\366te': ['flute']})
>>> d1==d2==d3==d4
```

Caution:

Don't initialise with a sequict instance when one or more values of the sequict instance meet following condition:

```
type(value) == type([])
```

Example:

```
>>> e=seqdict.mseqdict({'example':[]})
>>> e
seqdict(
['example'],
{'example': [[]]})

#don't initialise when one or more value(s) of the seqdict instance is a
list type or list emulation:
>>> seqdict.mseqdict(e) #wrong
Traceback (innermost last):
   File "<stdin>", line 1, in ?
   File "seqdict/py", line 35, in __init__
        for key,value in List:
   File "ndict/py", line 57, in __getitem__
        return self.dict[key]
KeyError: 0
```

```
>>> seqdict.mseqdict(e.items()) #right, initialise with items instead
mseqdict(
['example'],
{'example': [[]]})
```

Things which will not work:
